Adaptive Business Rules Framework for Workflow Management

Kanana Ezekiel, Dr. Vassil Vassilev, Prof. Karim Ouazzane and Yogesh Patel

School of Computing & Digital Media, London Metropolitan University, UK

Abstract

**Purpose** – Changing scattered and dynamic business rules in Business Workflow Systems has become a growing problem that hinders the use and configuration of workflow-based applications. There is a gap in the existing research studies which currently focus on solutions that are application specific, without accounting for the universal logical dependencies between the business rules and, as a result, do not support adaptation of the business rules in real time. **Design/methodology/approach** – To tackle the above problems, this paper adopts a bottom-up approach, which puts forward a component model of the business process workflows and business rules based on purely logical specification which allows incremental development of the workflows and indexing of the rules which govern them during the initial acquisition and real-time execution. **Results** – The paper introduces a component-based event-driven model for development of business workflows which is purely logic-based and can be easily implemented using an object-oriented technology together with a formal model for accounting the business rules dependencies together with a new method for incremental indexing of the business rules controlling the workflows. It proposes a two-level inference mechanism as a vehicle for controlling the business process execution and adaptation of the business rules at real time based on propagating the dependencies between the rules. **Originality/value** – The major achievement of this research is the universal, strictly logic-based event-driven framework for business process modelling and control which allows automatic adaptation of the business rules governing the business workflows based on accounting for their structural dependencies. An additional advantage of the framework is its support for object-oriented technology which can be implemented with enterprise-level quality and efficiency. Although developed primarily for application in construction industry the framework is entirely domain-independent and can be used in other industries, too.

**Paper type** Research paper
Introduction

Almost all workflow applications are based on some sort of rule-based systems. Business rules control the behaviour of the business processes according to the domain logic and the best practices in the domain (Rowe, Stephens & Guo, 2004). For example, in a data centre workflow application, a rule may exist to ensure rack utilization is less than rack capacity before the equipment installation process is executed. The biggest strength behind the use of business rules come from having multiple and changing business rules interacting with each other. However, as more and more rules are added and rule inter-relations are established business rules require extensive work in order to maintain their consistency. In business environment, an essential element for success is the degree to which the rules can quickly change and propagate these changes in real time. This paper presents a novel approach to automate workflow processes using a framework of business rules, meta-rules and business rules relationships. The approach introduces a component-based and event-driven model for development of the business workflows which is based purely on logic and is implemented using an object-oriented technology. A formal model for accounting business rules and dependencies together with a new method for incremental indexing of business rules controlling workflows is described. The paper is structured as follows: First, a review of related literature and applications is examined. Second, a framework for business rules model specifically introducing our approach is presented. Third, an ontology of two-levels rule-based approach introducing building blocks of business rules model is provided. Fourth, we describe formal definitions and model concepts transformation into dependency trees for business rules relationships. Fifth, presents a preliminary implementation work using DROOLS and future work. Finally, some implications of the new approach have been identified and discussed briefly before the final conclusion.

Related Literature and Applications Review

The trend in research studies of rule-governed business workflows is focused primarily on theories and practices of custom-tailored workflows and much less on exploring business rules dependencies and the necessity of adapting the rules to the changing conditions. There are several popular Business Rules Management Systems (BRMS) on the market today, but it is still very difficult to configure and automate workflow applications as the study by Cognizant revealed (Cognizant, 2015). To name the few, BRMSs have been explore by various authors such as Al Hilwa & Hendrick (2012), Macdonald (2010), Sainte Marie (2011), Haley (2013), Feldman (2011), Boyer and Mili (2011), Browne (2009) and others. In the typical case, the BRMSs use a rule engine for business rules management, providing APIs for modelling business rules and algorithmic inference. However, there are notable limitations of the possibility to manage the changes, which require updating the formulation of business rules. Although BRMSs in most cases allow for rules to be specified separately from the business processes, which supports two-step procedure of business process modelling and business rules specification, it remain impossible to specify the dependencies between the rules based on the relationships between workflow objects. This causes multiple changes to be necessary to adjust already configured workflows and to update existing business rules even in the case of simple change. The main reason for this situation is the lack of consistent model of the components of the business rules themselves. Typically, rules are composed out of events, conditions and actions, which are specified separately and are not related through the objects used to formulate them. This means that change made on the “condition” part of a rule will require invoking the whole rule rather than only the condition component. Externalizing different part of the rules would bring flexibility and increase the performance as only that part which needs changing would be processed explicitly, while the adjustment can be automated.

Some research studies suggest more flexible approaches towards workflow systems automation. Casati et al. (2000), for example, consider a workflow design based on rule-based approach to handle exceptions based on a separate description of workflow activities. Their approach provides a higher degree of flexibility during workflow design since it allows to model exceptional situations. Still, it remains difficult to describe and account the dependencies between the rules. It becomes even more complicated to deal with multiple changing rules as the rule management remains a tedious manual task. In fact, this is one of the main reasons why rule-based approaches have not been popular choice for managing workflows. Goh et al. (2001) investigate the use of Event Condition Action rules (ECA) to support workflows in product development. In their approach workflow activities are associated with ECA rules to govern how the activities which are executed. But the emphasis of their work is on high-level integration platform for building flexible workflows, rather than business rules, process structures and dependencies. Other authors in the literature such as Boyer & Mali (2011) and Anantaram (2007) suggested modelling of business rules as components themselves, separate from the business objects and the application logic. While the business user is free to define and modify the rules, the rules and their components are not defined in the same ontology. This approach does not allow rule classifications and the rule dependencies cannot be defined. Also, this separation hinders usability and adaptability of business rules. Geppert (1998) describes the implementation of an event-driven engine for distributed workflows, called EVE. To control the distributed workflows, they maintain an explicit list of events. Their approach addresses the problem of distributed events in
workflow execution by focusing on reactive event-based coordination and integration but because the inter-relations are not defined explicitly they still don’t offer much flexibility in controlling the workflows in real time.

Framework for the Business Rules Model

To address issues discussed previously, we adopt an approach which relies on object-oriented modelling paradigm. The object orientation allows to define objects, classes and relationships between objects in a bottom-up manner, suitable for representing business rules complexities in a more structured and controllable manner. The formal model presented in this paper is based on the understanding of existing business workflow as an event-driven and constantly evolving process of incremental development, execution and control. This model operates on two levels, namely Workflow, or Process level (Figure 1) and Rule, or Control level (Figure 2). The business rules are building blocks that control workflows and they are made up of event, condition and action components, or the famous “When <event> If <condition> Then <action>” structure, whereas the workflows are made up of business processes (directed structures), process steps (primitive procedures), process flows (material and information links between processes), roles, etc. For instance, if some events are observed during execution of a working process then the corresponding business rules which depend on these events are invoked and lead to actions which in turn perform the transition to a new step which may execute other processes or amend the parameters of the current process. The model uses business rules to glue together processes from start to finish in a workflow (Figure 1).

The business rules apply at various stages of execution of the workflow - Initiation, Execution and Termination rules (Figure 3). Based on the different role they play in relation to the workflow they can be organised in a kind of taxonomic hierarchy: Execution rules are divided into Flow and Process rules, Flow rules are divided into Sequence, Fork and Join rules and Process rules are classified into Time based and Non-Time-based rules.
Additional rules known as **Data rules** (not covered in this paper) may be considered when some conditions are applicable directly to the input and output data in order to maintain the integrity of the flow.

![Rules Classification](image)

**Figure 3: Rules Classification**

### An ontology of the rule-based framework

This section presents the basic ontology of objects used to construct the workflows and the rules which govern them. It has been developed in a purely logical manner. All examples have been illustrated using DFD diagrams.

#### I. Objects

The objects are the building blocks for describing business processes, rules and workflows.

#### Example 1

Consider the workflow in Figure 4. It defines Business Rule “When install new equipment (Server), if Rack Space Utilization is greater than the 80% of Rack Capacity then send message”. Analysing the above example, the following concepts can be identified:
- 4 Processes: (Create Request to install new Server, Manage Rack Space Availability, Send Message and Order New Rack). Identify different work units that need to be accomplished.
- 2 Roles: Requestor, DC Manager which has not been covered in this paper.
- 1 Flow: Capturing data/material and information in and out the processes. Rack Capacity, Rack Utilization, New Equipment and even the Request are examples of Information and Material flows.
- Initiation Rule:
  - Start event - Workflow can be manually or automatically started by the use of initiation or triggering events. The business processes can be started only by Initiation rules after a suitable triggering event.
- Execution Rule:
  - Event - triggers or kick starts the rule: “When Install new equipment”
  - Condition - criteria for the rule to execute: “If rack utilization is greater than 80% of rack capacity”
  - Action - can be performed within the workflow or externally by the users of the workflow. In the example above, action response after the condition is satisfied is “send message”.
- Termination Rule:
  - End event - Workflow can be manually or automatically ended by the use of termination event trigger. The workflow termination is always based on termination rule, invoked by suitable termination event AFTER the process is finished, or on process execution rule DURING execution in the case of emergency

In Example 1 above, the Execution Rule is used to check rack space availability. The decision to install a new server onto a rack depends on the rule. Through the event “When Install new equipment”, the rule links two processes “Manage Rack Space Availability” and “Order New Rack”. The event “When Install new equipment” is observed in relation to process “Create Request to install new server” then the rule which depends on this event is invoked and lead to an action which performs the transition to “Order New Rack” process.

Following the terminology of the object models of Grady Booch (1994) and Umeshwar Dayal, et al. (2005), we refer to Process, Flow (Material, Information) and Rule (Event, Condition and Action) as first class objects.

II. Object Properties

Informally speaking, the business rules and workflows can be constructed in terms of object characteristics. The object properties provide information about the characteristics of the objects. For example, the object “Process-21” may have as properties process id, name, status, creation date, etc. From the viewpoint of the conceptualization of our ontology, object properties can be classified onto one of the following types:

- Identification properties - example are process id, name, type, context, scope, etc.
- Qualitative description properties - these are categorical or nominal properties, which can be described only qualitatively – for example, current status, deviation, trend, etc.
- Quantitative description properties – these properties can be described using a fixed value, which can be estimated qualitatively or specified quantitatively- for example, the number of closed processes in a chemical plant.

Sun, Bo and Fox (2014) describe object properties as a common approach to specify characteristics or attributes of a real-world object instance, which in turn helps to understand how to interact with the object. An object property value may be of different primitive type, including numeric, nonnumeric (strings/text/etc.), Boolean, etc. Property may have a single or multiple values. By introducing property characterisation for each object, our model can fulfil the requirements for flexibility and maintainability of the formulation of Business Rules and the versatility of the Process Workflow.

Since the objects are building blocks of both the process workflows and the business rules which govern them, the object properties are the main vehicle for analysing the dependencies between the business rules themselves. They will be the bridge between the process ontology and the algorithm for propagating the changes in the business rules. The primary role of qualitative and quantitative property measures is to accurately describe object properties rather than the usual identification and classification. The more sophisticated properties, the more elaborated dependencies we can formulate. Some object properties may be used to identify, name and categorize the objects. Others may be used to quantify and qualify the objects. There are circumstances where qualitative and quantitative properties are also used for identification of an object. We can even introduce properties for “potentially active” characterisation of the objects, like reflexive regularities, directed constraints and associative interdependencies between the properties of several objects. For instance, Business Rules may involve an array of object properties with objective estimation based on value measurement along with highly subjective value
judgments based on qualitative estimations. Finally, using the object properties we can organise them into groups and hierarchies which enables the use of object-oriented technology.

III. Rules

The structure and the classification of business rules (Figure 3) is based on the famous Event-Condition-Action paradigm, Bry, et al (2006). Our framework considers the following types of rules:

**Initiation Rules (IR)**

We propose Initiation Rule (IR) to formally depict rules that specifically initiate a process. Depending on the conditions of the rule, the process can be launched and thus continue the workflow execution. Some Initiation rules are driven by events only, hence known as Start Event. As an example, Figure 5 presents Equipment Installation workflow of an organization with three processes “Create Request”, “Send Message” and “Order New Rack”. In the background, the initiation rule “When receive request start message then start” looks up and assigns “Create Request” process whenever the rule is invoked. The rule is invoked when request message is received.

**Event or Process Rules**

We propose the class Event Rule to group rules that are specifically defined on Processes during the execution of a workflow. An example of such an event rule is the rule which requires the drivers to stop when road traffic light colour changes to red (Figure 6).
Flow Rules

We propose the class Flow Rule (FR) to formally depict rules that specifically define the flow of workflow processes. All workflows depend on flow rules to progress from one process to another. In other words, flow rules determine the start process and the transition through a chain of processes until the workflow ends. Flow rules can move the workflow along a single chain of processes or split it into multiple pathways, thus forming an acyclic graph. For instance, a path can be established between “Create Request” and “Approve Request” processes to connect the two related processes in a workflow. Important flow patterns that will be covered in this research include sequence, parallel split and merge. From this perspective Flow Rules define the transition pattern and allow to order the business processes in the workflow dynamically at runtime.

Termination Rules (TR)

We propose the class Termination Rule (TR) to formally depict rules that specifically trigger the end of a workflow. Some Termination Rules are driven by events only, hence known as End Event. Figure 7 presents Equipment Installation workflow of an organization with three processes “Create Request”, “Send Message” and “Order New Rack”. In the background, the termination rule “When receive closing message then end” looks up and ends processes whenever the rule is invoked. The rule is invoked when the request message is received.
Relationships and dependencies between Business Rules

Business rules formal description

Consider a Business Rule set R containing a collection of rule samples controlling a particular workflow. A Rule set R has one or more related rules that has been put together to guide the movement of processes in the workflow. For instance, R may be made up of Initiation Rule, Flow Rule, Event or Process Rules and Termination Rule.

Let every Rule in R be expressed in terms of \{R_i\} where each Rule definition R_i consists of a collection of Event (E), Condition (C) and Action (A). We refer to E, C and A to represent sets of Events, Conditions and Actions respectively containing fragments of the Rule R. Now, let E be expressed in terms of \{E_i\} and C be expressed in terms of \{C_i\}. Also A be expressed in terms of \{A_i\}. In this research, we will use notation E_i(R_i), C_i(R_i) and A_i(R_i) where E_i \in E, C_i \in C and A_i \in A to represent Business Rule basic definition. Note that for simplicity reasons, if a part of the Business Rule has no importance in a discussion then it will be omitted. For example, C_i(R_i) and A_i(R_i) will represent a Business Rule that contains Conditions and Actions only.

Relation between the business rules

The existence of a dependency between two rules expresses that communication occurs between components (Event, Condition, and Action) of the Business Rule. For example, one Business Rule action may trigger conditions of other Business Rules or condition of one Business rule may depend on an event of another Business Rule. Therefore, Business Rules relationships can be described by analysing Business Rule components relationships. We consider the relationship between two rules to be represented by the symbol \( \rightarrow \). For example, \( R_1 \rightarrow R_2 \) means Rule 1 relates to Rule 2. If one of R_1 action activates event for R_2, we declare as A_i(R_i) \( \rightarrow \) E_j(R_j). Business Rules relationships can be analysed and declared in one of the following possible six ways:

i. \( E_i(R_1) \rightarrow E_j(R_2) \)

![Diagram](image1)

ii. \( E_i(R_1) \rightarrow C_j(R_2) \)

![Diagram](image2)

iii. \( E_i(R_1) \rightarrow A_j(R_2) \)

![Diagram](image3)
iv. $C_{1i}(R_1) \rightarrow C_{2j}(R_2)$

v. $C_{1i}(R_1) \rightarrow A_{2j}(R_2)$

vi. $A_{1i}(R_1) \rightarrow A_{2j}(R_2)$

Figure 9: Structural Rule Dependencies

These relationships are defined based on Objects and Objects properties involved in Condition, Event and Action components of the Rules. Moreover, relationship can be defined in terms of qualitative and quantitative characteristics of the object parameters. We examined six ways (i-vi) of representing rule relationships based on the partial order relationship. However, it is far simpler and natural to apply the tree structure to model and picture the relationships between rules. Therefore, tree structure and patterns to show relationship are introduced next.

**Business rules dependency tree**

Structuring of the rules into an AND-OR tree according to their dependencies would allow implementing of more efficient algorithms for search of the rules. Furthermore, the different patterns of inclusion of the rules in the trees will be used inside the algorithms to control the flow of execution of the rules as the business processes progress at real-time. In addition, we can describe behaviour and flow dependency pattern of rules. For each dependency pattern, we can provide a visual representation of the rule dependency. It is important to understand that although
trees make it easier to understand the relationship between rules, they will need to be translated into rule language for workflow interpretation. Hence algorithms will be defined in additional to rule relationships definitions. The tree is constructed using nodes starting with the root of the tree going down to its leaves. The nodes will represent the Business Rules and edges represent relationships between rules. Tree structures such as decision trees are widely used to describe rules order and priorities; a tree can be made up of a large number of rules presented in analytical and visual manner Gizil Oguz, et al, (2008). In our model, navigation through tree nodes is attained by establishing relationships between rules components. As the name suggests AND/OR Tree, the relationships will be of two kinds. AND relationships, which group several rules that can be invoked simultaneously, and OR relationships, which group several rules that can be invoked alternatively. Variations of AND/OR relationships exist, including Direct AND Dependency, Direct OR Dependency, Indirect AND dependency and Indirect OR Dependency. Each pattern is illustrated in Figure 10a to 13c below. Our discussion in the rest of this section is confined to business rules relationships patterns and formal definitions.

i. **Direct AND Dependency patterns**

   A) Rule’s Event Relationships

   ![](image)

   Figure 10a: A Strong Direct AND Tree exemplifying Rule’s Event relationships

   The above tree represents a direct AND dependency where each node corresponds to the root node/rule \( E_i(R_i) \). The following patterns are depicted:

   - Direct edge \( (E_i(R_i), E_j(R_j)) \), with \( E_i \rightarrow E_j \), means that the event of rule \( R_i \) must influence the result of rule \( R_j \)’s event. This is \( E_i(R_i) \rightarrow \text{Relate to} \ E_j(R_j) \) relationship.
   - Direct edge \( (E_i(R_i), C_j(R_j)) \), with \( E_i \rightarrow C_j \), means that the event of rule \( R_i \) must influence the result of rule \( R_j \)’s condition. This is \( E_i(R_i) \rightarrow \text{Relate to} \ C_j(R_j) \) relationship.
   - Direct edge \( (E_i(R_i), A_j(R_j)) \), with \( E_i \rightarrow A_j \), means that the event of rule \( R_i \) must cause change to rule \( R_j \)’s action. This is \( E_i(R_i) \rightarrow \text{Relate to} \ A_j(R_j) \) relationship.
   - We can also depict the following possible combination of AND patterns:

     - \( E_i(R_i) \rightarrow \text{Relate to} \ E_j(R_j) \land E_k(R_k) \rightarrow \text{Relate to} \ C_j(R_j) \)
     - \( E_i(R_i) \rightarrow \text{Relate to} \ C_j(R_j) \land E_k(R_k) \rightarrow \text{Relate to} \ A_j(R_j) \)
     - \( E_i(R_i) \rightarrow \text{Relate to} \ E_j(R_j) \land E_k(R_k) \rightarrow \text{Relate to} \ A_j(R_j) \)
**B) Rule’s Condition Relationships**

This tree represents a direct AND dependency where each node corresponds to the root node/rule $C_{i1}(R_1)$. The following patterns are depicted:

- Direct edge ($C_{i1}(R_1), E_{2j}(R_2)$), with $C_{i1} \rightarrow E_{2j}$, means that the condition of rule $R_1$ must influence or trigger rule $R_2$’s event. This is $C_{i1}(R_1) \xrightarrow{\text{Relate to}} E_{2j}(R_2)$ relationship.

- Direct edge ($C_{i1}(R_1), C_{2j}(R_2)$), with $C_{i1} \rightarrow C_{2j}$, means that the condition of rule $R_1$ must influence the result of rule $R_2$’s condition. This is $C_{i1}(R_1) \xrightarrow{\text{Relate to}} C_{2j}(R_2)$ relationship.

- Direct edge ($C_{i1}(R_1), A_{2j}(R_2)$), with $C_{i1} \rightarrow A_{2j}$, means that the condition of rule $R_1$ must cause change to rule $R_2$’s action. This is $C_{i1}(R_1) \xrightarrow{\text{Relate to}} A_{2j}(R_2)$ relationship.

- We can also depict the following possible combination of AND patterns:

  - $C_{i1}(R_1) \xrightarrow{\text{Relate to}} E_{2j}(R_2) \land C_{i1}(R_1) \xrightarrow{\text{Relate to}} C_{2j}(R_2)$
  - $C_{i1}(R_1) \xrightarrow{\text{Relate to}} C_{2j}(R_2) \land C_{i1}(R_1) \xrightarrow{\text{Relate to}} A_{2j}(R_2)$
  - $C_{i1}(R_1) \xrightarrow{\text{Relate to}} E_{2j}(R_2) \land C_{i1}(R_1) \xrightarrow{\text{Relate to}} A_{2j}(R_2)$
  - $C_{i1}(R_1) \xrightarrow{\text{Relate to}} E_{2j}(R_2) \land C_{i1}(R_1) \xrightarrow{\text{Relate to}} C_{2j}(R_2) \land C_{i1}(R_1) \xrightarrow{\text{Relate to}} A_{2j}(R_2)$

**C) Relationships between Rule’s Action and the Conditions/Events of another rule**

This tree shows the AND dependency between the action of rule $R_1$ and the conditions/events of rule $R_2$. The following patterns are depicted:

- Action edge ($A_{11}(R_1), E_{2j}(R_2)$), with $A_{11} \rightarrow E_{2j}$, means that the action of rule $R_1$ must influence or trigger rule $R_2$’s event. This is $A_{11}(R_1) \xrightarrow{\text{Relate to}} E_{2j}(R_2)$ relationship.

- Action edge ($A_{11}(R_1), C_{2j}(R_2)$), with $A_{11} \rightarrow C_{2j}$, means that the action of rule $R_1$ must influence the result of rule $R_2$’s condition. This is $A_{11}(R_1) \xrightarrow{\text{Relate to}} C_{2j}(R_2)$ relationship.

- Action edge ($A_{11}(R_1), A_{2j}(R_2)$), with $A_{11} \rightarrow A_{2j}$, means that the action of rule $R_1$ must cause change to rule $R_2$’s action. This is $A_{11}(R_1) \xrightarrow{\text{Relate to}} A_{2j}(R_2)$ relationship.

Figure 10b: A Strong Direct AND Tree exemplifying Rule’s Condition relationships

Figure 10c: A Strong Direct AND Tree exemplifying Rule’s Action relationships
This tree represents a direct AND dependency where each node corresponds to a root node/rule $A_{1i}(R_1)$. The following patterns are depicted:

- **Direct edge** $(A_{1i}(R_1), E_{2j}(R_2))$, with $A_{1i} \rightarrow E_{2j}$, means that the action of rule $R_1$ must influence the result of rule $R_2$’s event. This is $A_{1i}(R_1) \xrightarrow{Relate to} E_{2j}(R_2)$ relationship.
- **Direct edge** $(A_{1i}(R_1), C_{2j}(R_2))$, with $A_{1i} \rightarrow C_{2j}$, means that the action of rule $R_1$ must influence the result of rule $R_2$’s condition. This is $A_{1i}(R_1) \xrightarrow{Relate to} C_{2j}(R_2)$ relationship.
- We can also depict the following possible combination of AND pattern:
  
  $A_{1i}(R_1) \xrightarrow{Relate to} E_{2j}(R_2) \land A_{1i}(R_1) \xrightarrow{Relate to} C_{2j}(R_2)$

Consider patterns identified from Figure 10a-c. Such dependency patterns only appear when there is a strong relationship between one of more rules. The patterns are based on an AND join, one node (rule) is directly joined to another node (rule) through related components (event, condition, action). The relationship may include relation between objects, quantitative estimation of a property, and qualitative estimation of a property as well as relation between properties of objects/ components (event, condition, and action). A combination of nodes (rules) can also be linked through an AND join.

ii. **Direct OR Dependency patterns**

  A) **Rule’s Event Relationships**

![Figure 11a: A Weak Direct OR Tree exemplifying Rule’s Event relationships](image)

This tree represents a direct OR dependency where the following possible combination patterns are depicted when $E_{1i}(R_1)$ is a root node/rule:

- The execution of $E_{1i}(R_1)$ may or may not trigger the execution of $E_{2j}(R_2)$ depending on additional events, conditions or actions from the class, or guarded by external events so each of these cases introduces different degree of “weakness”
- The execution of $E_{1i}(R_1)$ may or may not trigger the execution of $C_{2j}(R_2)$ depending on additional events, conditions or actions from the class, or guarded by external events.
- The execution of $E_{1i}(R_1)$ may or may not trigger the execution of $A_{2j}(R_2)$ depending on additional events, conditions or actions from the class, or guarded by external events.
- We can also depict the following possible combination of OR patterns:
  
  $E_{1i}(R_1) \xrightarrow{Relate to} E_{2j}(R_2) \lor E_{1i}(R_1) \xrightarrow{Relate to} C_{2j}(R_2)$
  $E_{1i}(R_1) \xrightarrow{Relate to} C_{2j}(R_2) \lor E_{1i}(R_1) \xrightarrow{Relate to} A_{2j}(R_2)$
  $E_{1i}(R_1) \xrightarrow{Relate to} E_{2j}(R_2) \lor E_{1i}(R_1) \xrightarrow{Relate to} A_{2j}(R_2)$
B) Rule’s Condition Relationships

This tree represents a direct OR dependency where the following possible combination node patterns are depicted when C(i(R1)) is a root node/rule:

- The execution of C(i(R1)) may or may not trigger the execution of E(j(R2)) depending on additional events, conditions or actions from the class, or guarded by external events so each of these cases introduces different degree of “weakness”
- The execution of C(i(R1)) may or may not trigger the execution of C(j(R2)) depending on additional events, conditions or actions from the class, or guarded by external events
- The execution of C(i(R1)) may or may not trigger the execution of A(j(R2)) depending on additional events, conditions or actions from the class, or guarded by external events
- We can also devise the following possible combination of OR patterns:

  o C(i(R1)) \xrightarrow{\text{Relate to}} E(j(R2)) \lor C(i(R1)) \xrightarrow{\text{Relate to}} C(j(R2))
  o C(i(R1)) \xrightarrow{\text{Relate to}} C(j(R2)) \lor C(i(R1)) \xrightarrow{\text{Relate to}} A(j(R2))
  o C(i(R1)) \xrightarrow{\text{Relate to}} E(j(R2)) \lor C(i(R1)) \xrightarrow{\text{Relate to}} A(j(R2))
  o C(i(R1)) \xrightarrow{\text{Relate to}} E(j(R2)) \lor C(i(R1)) \xrightarrow{\text{Relate to}} C(j(R2)) \lor C(i(R1)) \xrightarrow{\text{Relate to}} A(j(R2))

C) Relationships between Rule’s Action and the Conditions/Events of another rule

This tree represents a direct OR dependency where the following possible combination node patterns are depicted when C(i(R1)) is a root node/rule:

- The execution of C(i(R1)) may or may not trigger the execution of E(j(R2)) depending on additional events, conditions or actions from the class, or guarded by external events so each of these cases introduces different degree of “weakness”
- The execution of C(i(R1)) may or may not trigger the execution of C(j(R2)) depending on additional events, conditions or actions from the class, or guarded by external events
- The execution of C(i(R1)) may or may not trigger the execution of A(j(R2)) depending on additional events, conditions or actions from the class, or guarded by external events
- We can also devise the following possible combination of OR patterns:

  o C(i(R1)) \xrightarrow{\text{Relate to}} E(j(R2)) \lor C(i(R1)) \xrightarrow{\text{Relate to}} C(j(R2))
  o C(i(R1)) \xrightarrow{\text{Relate to}} C(j(R2)) \lor C(i(R1)) \xrightarrow{\text{Relate to}} A(j(R2))
  o C(i(R1)) \xrightarrow{\text{Relate to}} E(j(R2)) \lor C(i(R1)) \xrightarrow{\text{Relate to}} A(j(R2))
  o C(i(R1)) \xrightarrow{\text{Relate to}} E(j(R2)) \lor C(i(R1)) \xrightarrow{\text{Relate to}} C(j(R2)) \lor C(i(R1)) \xrightarrow{\text{Relate to}} A(j(R2))
The above tree represents a direct OR dependency where the following possible combination patterns are depicted when A_{1i}(R_1) is a root node/rule:

- The execution of A_{1i}(R_1) may or may not trigger the execution of E_{2j}(R_2) depending on additional events, conditions or actions from the class, or guarded by external events so each of these cases introduces different degree of “weakness”
- The execution of A_{1i}(R_1) may or may not trigger the execution of C_{2j}(R_2) depending on additional events, conditions or actions from the class, or guarded by external events
- We can also devise the following possible combination of OR patterns:
  - A_{1i}(R_1) \rightarrow E_{2j}(R_2), A_{1i}(R_1) \rightarrow C_{2j}(R_2)

Consider patterns identified from Figure 11a-c. Such dependency patterns only appear when there is a weak relationship between one or more rules. These dependency patterns are based on an OR join, one node (rule) is directly joined to another node (rule) through related components (event, condition, action). The relationship may include relation between objects, quantitative estimation of a property, and qualitative estimation of a property as well as relation between properties of objects/components (event, condition, and action). A combination of nodes (rules) can also be linked through an OR join.

iii. **Indirect AND Dependency patterns**

A) **Rule’s Event AND-Relationship**

The tree below represents indirect AND dependency where nodes are indirectly connected to the root node/rule E_{1i}(R_1) through nodes/rules (X, Y, Z).

![Diagram](image)

Figure 12a: Strong Indirect AND Tree exemplifying Rule’s Event AND-Relationships

The following relationship patterns are depicted:

- Edge (E_{1i}(R_1), X); (X, E_{2j}(R_2)), with E_{1i} \rightarrow X; X \rightarrow E_{2j}, means that the event of rule R_1 is indirectly influencing the result of rule R_2’s event through rule X. The relationship consists of pairs E_{1i}(R_1) \rightarrow X and X \rightarrow E_{2j}(R_2). By the transitivity relation property, Di Nola A (1991) E_{1i}(R_1) \rightarrow E_{2j}(R_2)
- Edge (E_{1i}(R_1), Y); (Y, C_{2j}(R_2)), with E_{1i} \rightarrow Y; Y \rightarrow C_{2j}, means that the event of rule R_1 is indirectly influencing the result of rule R_2’s condition through rule Y. The relationship consists
of pairs \(E_1(R_1) \rightarrow Y\) and \(Y \rightarrow C_2(R_2)\). By the transitivity relation property, Di Nola A (1991) \(E_1(R_1) \rightarrow C_2(R_2)\).

- Edge \((E_1(R_1), Z); (Z, A_2(R_2))\), with \(E_1 \rightarrow Z; Z \rightarrow A_2\), means that the event of rule \(R_1\) is indirectly causing change to rule \(R_2\)’s action through rule \(Z\). The relationship consists of pairs \(E_1(R_1) \rightarrow Z\) and \(Z \rightarrow A_2(R_2)\). By transitivity relation property, Di Nola A (1991) \(E_1(R_1) \rightarrow A_2(R_2)\).

- We can also depict the following possible combination of AND-relationship patterns:

\[
\begin{align*}
\text{Edge } (E_1(R_1), X); (X, E_2(R_2)) \Rightarrow E_1(R_1) \rightarrow E_2(R_2) & \land E_1(R_1) \rightarrow C_2(R_2) \\
\text{Edge } (E_1(R_1), C_2(R_2)); (C_2(R_2), A_2(R_2)) \Rightarrow E_1(R_1) \rightarrow C_2(R_2) & \land E_1(R_1) \rightarrow A_2(R_2) \\
\text{Edge } (E_1(R_1), E_2(R_2)); (E_2(R_2), C_2(R_2)) \Rightarrow E_1(R_1) \rightarrow E_2(R_2) & \land E_1(R_1) \rightarrow C_2(R_2) \\
\end{align*}
\]

C) Rule’s Condition AND-Relationship

The tree below represents an indirect AND dependency where nodes are indirectly connected to the root node/rule \(C_1(R_1)\) through rules \((X,Y,Z)\).

![Figure 12b: Strong Indirect AND Tree exemplifying Rule’s Condition AND-Relationships](image)

The following patterns are depicted:

- Edge \((C_1(R_1), X); (X, E_2(R_2))\), with \(C_1 \rightarrow X; X \rightarrow E_2\), means that the condition of rule \(R_1\) is indirectly influencing or triggering rule \(R_2\)’s event through rule \(X\). The relationship consists of pairs \(C_1(R_1) \rightarrow X\) and \(X \rightarrow E_2(R_2)\). By the transitivity relation property, Di Nola A (1991) \(C_1(R_1) \rightarrow E_2(R_2)\).

- Edge \((C_1(R_1), Y); (Y, C_2(R_2))\), with \(C_1 \rightarrow Y; Y \rightarrow C_2\), means that the condition of rule \(R_1\) is indirectly influencing the result of rule \(R_2\)’s condition through rule \(Y\). The relationship consists
of pairs $C_{1i}(R_{1}) \rightarrow Y$ and $Y \rightarrow C_{2j}(R_{2})$. By the transitivity relation property, Di Nola A (1991) $C_{1i}(R_{1}) \rightarrow C_{2j}(R_{2})$.

- Edge $(C_{1i}(R_{1}), Z)$; $(Z, A_{2j}(R_{2}))$, with $C_{1i} \rightarrow Z ; Z \rightarrow A_{2j}$, means that the condition of rule $R_{1}$ is indirectly affecting rule $R_{2}$’s action through rule $Z$. The relationship consists of pairs $C_{1i}(R_{1}) \rightarrow Z$ and $Z \rightarrow A_{2j}(R_{2})$. By transitivity relation property, Di Nola A (1991) $C_{1i}(R_{1}) \rightarrow A_{2j}(R_{2})$.

- We can also depict the following possible combination of AND-relationship patterns:
  - $C_{1i}(R_{1}) \rightarrow E_{2j}(R_{2}) \land C_{1i}(R_{1}) \rightarrow C_{2j}(R_{2})$
  - $C_{1i}(R_{1}) \rightarrow C_{2j}(R_{2}) \land C_{1i}(R_{1}) \rightarrow A_{2j}(R_{2})$
  - $C_{1i}(R_{1}) \rightarrow E_{2j}(R_{2}) \land C_{1i}(R_{1}) \rightarrow A_{2j}(R_{2})$
  - $C_{1i}(R_{1}) \rightarrow E_{2j}(R_{2}) \land C_{1i}(R_{1}) \rightarrow C_{2j}(R_{2}) \land C_{1i}(R_{1}) \rightarrow A_{2j}(R_{2})$

D) AND-Relationships between Rule’s Action and the Conditions/Events of another rule

**Figure 12c: Strong Indirect AND Tree exemplifying Rule’s Action AND-Relationships**

The above tree represents indirect AND dependency where nodes are indirectly connected to the root node/rule $A_{1i}(R_{1})$ through rules (X,Y). The following patterns are depicted:

- The execution of $A_{1i}(R_{1})$ indirectly triggers the execution of $E_{2j}(R_{2})$ through additional events, conditions or actions of the X rule. The relationship consists of pairs $A_{1i}(R_{1}) \rightarrow X$ and $X \rightarrow E_{2j}(R_{2})$. By the transitivity relation property, Di Nola A (1991) $A_{1i}(R_{1}) \rightarrow E_{2j}(R_{2})$.

- The execution of $A_{1i}(R_{1})$ indirectly triggers the execution of $C_{2j}(R_{2})$ through additional events, conditions or actions from Y rule. The relationship consists of the pairs $A_{1i}(R_{1}) \rightarrow Y$ and $Y \rightarrow C_{2j}(R_{2})$. By the transitivity relation property, Di Nola A (1991) $A_{1i}(R_{1}) \rightarrow C_{2j}(R_{2})$.

- We can also devise the following possible combination of AND-relationship patterns:
  - $A_{1i}(R_{1}) \rightarrow E_{2j}(R_{2}) \land A_{1i}(R_{1}) \rightarrow C_{2j}(R_{2})$

The “Indirect AND Dependency” pattern (Figure 12a-c) is such that rule nodes flow into two or more edges; the edges proceed and merge into a rule node where a connection or relationship is to be established, hence indirectly connected through intermediate nodes. This dependency pattern is based
indirect AND connections between nodes or rules on the same path. There must be at least one indirect rule from the nodes with an AND connection.

iv. **Indirect OR Dependency patterns**

A) **Rule’s Event OR-Relationship**

The tree below represents indirect OR dependency where nodes are indirectly connected to the root node/rule $E_{1i}(R_1)$ through nodes/rules $(X, Y, Z)$.

![Weak Indirect OR Tree](image)

**Figure 13a: Weak Indirect OR Tree exemplifying Rule’s Event OR-Relationships**

The following patterns are depicted:

- Edge $(E_{1i}(R_1), X)$; $(X, E_{2j}(R_2))$, with $E_{1i} \rightarrow X \rightarrow E_{2j}$, means that the event of rule $R_1$ may or may not indirectly influence the result of rule $R_2$’s event. The relationship consists of pairs $E_{1i}(R_1) \rightarrow X$ and $X \rightarrow E_{2j}(R_2)$. By the transitivity relation property, Di Nola A (1991) $E_{1i}(R_1)$ $\rightarrow$ $E_{2j}(R_2)$.

- Edge $(E_{1i}(R_1), Y)$; $(Y, C_{2j}(R_2))$, with $E_{1i} \rightarrow Y \rightarrow C_{2j}$, means that the event of rule $R_1$ may or may not indirectly influence the result of rule $R_2$’s condition. The relationship consists of pairs $E_{1i}(R_1) \rightarrow Y$ and $Y \rightarrow C_{2j}(R_2)$. By the transitivity relation property, Di Nola A (1991) $E_{1i}(R_1)$ $\rightarrow$ $C_{2j}(R_2)$.

- Edge $(E_{1i}(R_1), Z)$; $(Z, A_{2j}(R_2))$, with $E_{1i} \rightarrow Z \rightarrow A_{2j}$, means that the event of rule $R_1$ may or may not indirectly cause change to rule $R_2$’s action. The relationship consists of pairs $E_{1i}(R_1) \rightarrow Z$ and $Z \rightarrow A_{2j}(R_2)$. By the transitivity relation property, Di Nola A (1991) $E_{1i}(R_1)$ $\rightarrow$ $A_{2j}(R_2)$.

We can also depict the following possible combination of OR patterns:

- $E_{1i}(R_1) \rightarrow E_{2j}(R_2) \lor E_{1i}(R_1) \rightarrow C_{2j}(R_2)$
- $E_{1i}(R_1) \rightarrow C_{2j}(R_2) \lor E_{1i}(R_1) \rightarrow A_{2j}(R_2)$
- $E_{1i}(R_1) \rightarrow E_{2j}(R_2) \lor E_{1i}(R_1) \rightarrow A_{2j}(R_2)$
- $E_{1i}(R_1) \rightarrow E_{2j}(R_2) \lor E_{1i}(R_1) \rightarrow C_{2j}(R_2) \lor E_{1i}(R_1) \rightarrow A_{2j}(R_2)$
B) Rule’s Condition OR-Relationship

The tree below represents indirect OR dependency where nodes are indirectly connected to the root node/rule C1(R1) through rules (X,Y,Z).

![Diagram of OR relationships]

Figure 13b: Weak Indirect OR Tree exemplifying Rule’s Condition OR-Relationships

The following patterns are depicted:

- Edge (C1(R1) X); (X, E2(R2)), with C1 → X; X OR → E2 means that the condition of rule R1 may or may not indirectly influence or trigger rule R2’s event. The relationship consists of pairs conclude C1(R1) Relate to X and conclude X Relate to E2(R2). By the transitivity relation property, Di Nola A (1991) C1(R1) Relate to E2(R2).

- Edge (C1(R1) Y); (Y, C2(R2)), with C1 → Y; Y OR → C2 means that the condition of rule R1 may or may not indirectly influence the result of rule R2’s condition. The relationship consists of pairs C1(R1) Relate to Y and Y Relate to C2(R2). By the transitivity relation property, Di Nola A (1991) C1(R1) Relate to C2(R2).

- Edge (C1(R1), Z); (Z, A2(R2)), with C1 → Z; Z OR → A2 means that the condition of rule R1 may or may not indirectly cause change to rule R2’s action. The relationship consists of pairs C1(R1) Relate to Z and Z Relate to A2(R2). By the transitivity relation property, Di Nola A (1991) C1(R1) Relate to A2(R2).

- We can also depict the following possible combination of OR patterns:
  - C1(R1) Relate to E2(R2) OR C1(R1) Relate to C2(R2)
  - C1(R1) Relate to C2(R2) OR C1(R1) Relate to A2(R2)
  - C1(R1) Relate to E2(R2) OR C1(R1) Relate to A2(R2)
  - C1(R1) Relate to C2(R2) OR C1(R1) Relate to C9(R2) OR C1(R1) Relate to A2(R2)

C) OR-Relationships between Rule’s Action and the Conditions/Events of another rule

The tree below represents an indirect OR dependency where nodes are indirectly connected to the root node/rule A1(R1) through rules (X,Y).
Figure 13c: Weak Indirect OR Tree exemplifying Rule’s Action OR-Relationships

The following patterns are depicted:

- The execution of \( A_i(R_1) \) may or may not indirectly triggers the execution of \( E_j(R_2) \) depending on additional events, conditions or actions from \( X \) rule. The relationship consists of pairs \( A_i(R_1) \) \( \rightarrow \) \( X \) and \( X \) \( \rightarrow \) \( E_j(R_2) \). By the transitivity relation property, Di Nola A (1991) \( A_i(R_1) \) \( \rightarrow \) \( E_j(R_2) \).

- The execution of \( A_i(R_1) \) may or may not indirectly trigger the execution of \( C_j(R_2) \) depending on additional events, conditions or actions from \( Y \) rule. The relationship consists of pairs \( A_i(R_1) \) \( \rightarrow \) \( Y \) and \( Y \) \( \rightarrow \) \( C_j(R_2) \). By the transitivity relation property, Di Nola A (1991) \( A_i(R_1) \) \( \rightarrow \) \( C_j(R_2) \).

- We can also devise the following possible combination of OR patterns:

\[
A_i(R_1) \lor A_i(R_1) \rightarrow E_j(R_2) \lor C_j(R_2)
\]

The “Indirect OR Dependency” pattern (Figure 13a-c) is such that rule nodes flow into two or more edges; the edges proceed and merge into a rule node where connection or relationship is to be established, hence are indirectly connected through intermediate nodes. This dependency pattern is based on an indirect OR connections between nodes or rules on the same path. There must be at least one indirect rule from the nodes with an OR connection.

All relationship patterns presented in (i) to (iv) are formally defined as follows:

1. Direct AND Dependency
(2) Direct OR Dependency

\[ \forall R_1, R_2 \quad R_1 \lor R_2 \quad \Rightarrow \quad R_2 \]

\[ \begin{align*}
E_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \lor \\
E_{1}(R_1) & \quad \Rightarrow \quad C_{2}(R_2) \quad \lor \\
E_{1}(R_1) & \quad \Rightarrow \quad A_{2}(R_2) \quad \lor \\
E_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \lor \quad E_{1}(R_1) \quad \Rightarrow \quad C_{2}(R_2) \quad \lor \\
E_{1}(R_1) & \quad \Rightarrow \quad C_{2}(R_2) \quad \lor \quad E_{1}(R_1) \quad \Rightarrow \quad A_{2}(R_2) \quad \lor \\
E_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \lor \quad E_{1}(R_1) \quad \Rightarrow \quad A_{2}(R_2) \quad \lor \\
E_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \lor \quad E_{1}(R_1) \quad \Rightarrow \quad C_{2}(R_2) \quad \lor \quad E_{1}(R_1) \quad \Rightarrow \quad A_{2}(R_2) \quad \lor \\
C_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \lor \\
C_{1}(R_1) & \quad \Rightarrow \quad C_{2}(R_2) \quad \lor \\
C_{1}(R_1) & \quad \Rightarrow \quad A_{2}(R_2) \quad \lor \\
C_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \lor \quad C_{1}(R_1) \quad \Rightarrow \quad C_{2}(R_2) \quad \lor \\
C_{1}(R_1) & \quad \Rightarrow \quad C_{2}(R_2) \quad \lor \quad C_{1}(R_1) \quad \Rightarrow \quad A_{2}(R_2) \quad \lor \\
C_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \lor \quad C_{1}(R_1) \quad \Rightarrow \quad C_{2}(R_2) \quad \lor \quad C_{1}(R_1) \quad \Rightarrow \quad A_{2}(R_2) \quad \lor \\
A_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \lor \\
A_{1}(R_1) & \quad \Rightarrow \quad C_{2}(R_2) \quad \lor \\
A_{1}(R_1) & \quad \Rightarrow \quad A_{2}(R_2) \quad \lor \\
A_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \lor \quad A_{1}(R_1) \quad \Rightarrow \quad C_{2}(R_2) \quad \lor \\
C_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \lor \\
\end{align*} \]

(3) Indirect AND Dependency

\[ \forall R_1, R_2 \quad R_1 \land R_2 \quad \Rightarrow \quad R_2 \]

\[ \begin{align*}
E_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \land \\
E_{1}(R_1) & \quad \Rightarrow \quad C_{2}(R_2) \quad \land \\
E_{1}(R_1) & \quad \Rightarrow \quad A_{2}(R_2) \quad \land \\
E_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \land \quad E_{1}(R_1) \quad \Rightarrow \quad C_{2}(R_2) \quad \land \\
E_{1}(R_1) & \quad \Rightarrow \quad C_{2}(R_2) \quad \land \quad E_{1}(R_1) \quad \Rightarrow \quad A_{2}(R_2) \quad \land \\
E_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \land \quad E_{1}(R_1) \quad \Rightarrow \quad A_{2}(R_2) \quad \land \\
E_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \land \quad E_{1}(R_1) \quad \Rightarrow \quad C_{2}(R_2) \quad \land \quad E_{1}(R_1) \quad \Rightarrow \quad A_{2}(R_2) \quad \land \\
C_{1}(R_1) & \quad \Rightarrow \quad E_{2}(R_2) \quad \land \\
\end{align*} \]
Indirect OR Dependency

The relationship is defined by directly linking the objects and indirectly relating the quantitative and qualitative estimation of their properties. Although the relationship patterns are different in terms of their semantics, they also bear some similarities in terms of the appearance of different components of the rules in the structures representing their use in real time. For example, in Figure 14 we can identify the following patterns of dependency between rules: rules on the same path (also known as chained rules, shown in the same color), rules on the same level (alternative rules), rules with the same parents (alternative chains), directly related rules, indirectly related rules, etc.
The AND/OR Tree (Figure 14) combines all relationship patterns presented earlier. Now, let us describe various dependency patterns found in the AND/ OR Tree:

**Precedence based dependencies:** The relationship between Rules is formed by using either successor or predecessor rules. This relationship can be identified when within the same root, parent-child or sibling nodes are related.

**Level based dependencies:** Nodes (Rules) at the same levels are connected by using root nodes. The relationship between Rules can be defined based on the levels in the tree. The relationship can form multilevel dependencies as well. Furthermore, this pattern can form an AND or OR relationship pattern.

**Path based dependencies:** Nodes (Rules) on the same paths are connected consecutively from the top node to the leaf nodes.

**Node based dependencies:** Nodes (Rules) without the same root, parent-child or sibling can be related. The relationship can be defined solely based on individual node (rule) properties that invoke other Rules. Here the relationship may result in a non-tree structure and can be inefficient for a large set of rules since every node’s relationship is to be checked. However, we argue that this is a reasonable relationship since those properties with dependence can be achieved by establishing rule property class dependencies.

**Indirect node based dependencies:** The dependency is established through intermediate nodes on the same root node. AND and OR Indirect node dependencies variations exist.

The AND/ OR Tree may be considered as a set of rule dependency patterns that have similar behaviour and shapes. We can distinguish a dependency pattern subset using $\text{AOT}_{\text{pattern}} \subseteq \text{AOT}$ to represent different dependency patterns as described in 1-5 above. A dependency pattern consists of a set of nodes $\{R_i\} = \{1, \ldots, n\}$. A distinguished node called root$R_i$ and a mapping (relationship): root$R_i \rightarrow R_i$ relating a node with its parent node. Any given rule...
dependency pattern type may have a default meta-rule dependency established. Derived classes created from base classes through process of inheritance can inherit a dependency type and override the meta-rules based on relationships.

**Implementation**

Dependencies between rules are formulated using objects which are parameters of their conditions, events and actions, hence the building of the dependency tree can be done using an incremental algorithm as the rules are added to the repository. Since the events, conditions and actions of the rules can be implemented as separate objects, the algorithms for processing the dependency tree can be based on rules operating on the same objects (meta-rules). This approach allows to use the object-oriented technology of programming for indexing. We have implemented a pilot of the framework using the open source rule management systems DROOLS, Proctor, et al. (2011). To provide high level of adaptation, each component of the rules is implemented as an atomic Java class which can be executed directly in Drools classes. Business rule classes (Event, Condition, Action) are associated with a rule (Rule) and workflow class (Flow). Business rules classification is implemented using the class inheritance concept as discussed in Aliverti et al (2016). Figure 15 presents an example of Condition Class implementation:

```java
//Condition class implementation - setting properties and methods
//i.e. setter and getters
Package com.ABR1w.model;
Public class Condition {
    //Properties declarations
    Private String Condition_Object;
    Private String Condition_Property;
    Private String AND;
    Private String OR;
    //Methods
    Public String getConditionObject () {
        return ConditionObject;
    }
    Public void setConditionObject (String ConditionObject){
        this.ConditionObject = ConditionObject;
    }
    ...  
}
```

Figure 15 Implementation of Condition Class

In additional to the representation of business objects in DROOLS, currently we are working on a series of algorithms for propagating the changes and logical analysis of the rules accounting the structural dependencies between them. Also under way is the implementation of two separate inference engines: a forward chaining inference engine for process workflow management, invoked by the events captured during execution, and a backward chaining inference engine for reorganising the rules, which propagates the changes and adapts to the changing state of control at real-time.

**Conclusion and future work**

The framework presented in this paper introduces a two-level model for business rules governed process workflows which is based on strict logical formalization of the business ontology. It allows the use of object-oriented technology for modelling workflows and business rules while providing a seamless mechanism for incremental indexing of the business rules by accounting their logical dependencies. This can also be used to propagate the changes amongst the rules in real time which can influence activities and operations in many business workflows today. Although our primary interest is to apply the framework to the business processes typical in the construction industry we believe our approach has much wider potential due to its strictly logical formalisation and domain independence. The framework could be applied to both large business process modelling tasks and small but very dynamic business processes like the typical digital business processes found in online banking or e-Commerce. It can be also interesting for adjusting rule-based policies in the case of changing conditions, typical in cyber security area. The effect of adding the capability to adapt automatically the access rights in order to account the new resources and new channels can have a huge impact in this area.
