Abstract—Circuit simulation is widely used in communication and control equipment hardware design tasks. This article introduces an extended version of the popular Qucs circuit simulator called Qucs-0.0.19S. It is a simulation tool which supports multiple SPICE circuit simulators, including Ngspice and Xyce. The package includes a graphical user interface, component and compact device modelling tools, a choice of simulation engine, and advanced simulation data postprocessing facilities. It allows user to construct new component using XSPICE extension and construct new simulations using Nutmeg scripting. Qucs-0.0.19S is targeted at academic and industrial applications. Software implementation details and application cases are considered.

Index Terms—Qucs, SPICE, Ngspice, Xyce, Nutmeg scripting, circuit simulation, EDA

I. INTRODUCTION

Open source software offers access and cost benefits to enterprise information technology. However, not all sectors have a fully developed software base. One example is electronic design automation (EDA) where General Public Licence (GPL) circuit simulation and printed circuit board layout packages are undergoing rapid development. The "Quite universal circuit simulator" (Qucs) [1], [2] is one of a new breed of GPL circuit simulators. Qucs was started by M. Margraf and S. Jahn in 2001. The initial intention was that Qucs should be an RF circuit analysis package which offered features not found in SPICE. Recently a new team took over responsible for Qucs development.

Qucs-0.0.19S is a freely available package with versions for Linux, Windows © and MacOS © . It includes a simulation kernel called Qucsator. Although Qucsator has acceptable performance it is not fully compatible with SPICE 2g6 or 3f5 [3], [4]. Qucs has a unique netlist syntax and model format with SPICE support implemented via a software compatibility layer. It does not allow direct access to manufacturers SPICE models and libraries. The compatibility layer also prohibits access to a number of SPICE built in models, simulation types and the Nutmeg scripting language. A "Spice4qucs" subsystem has been added to Qucs to form Qucs-0.0.19S [5], and hence overcome these limitations. Qucs-0.0.19S was presented during MOS-AK workshop at Graz, Austria [6].

Spice4qucs is not another SPICE simulation kernel but acts as an interface to a number of established GPL SPICE engines. These have excellent performance, but usually lack a graphical user interface (GUI) for schematic capture and

external simulator launch control. The reverse is true for Qucs which is distributed with mature GUI and modelling tools.

Evaluation of GPL SPICE simulators, plus feedback from Qucs users, suggested; (a) Qucs should support several SPICE GPL kernels, (b) Qucs should not simple be a schematic capture and simulation software package but must also offer advanced data processing features, and (c) provide a range of compact device modelling facilities. Factor (a) is met by the Ngspice [7] and XYCE [8] SPICE simulators. Moreover, Spice4qucs is able to launch both simulators from the Qucs GUI. Qucsator has excellent small signal AC and S-parameter simulation performance. But Qucsator time-domain simulation is not that stable. In particular, Qucsator cannot reliably simulate switching circuits. The addition of SPICE based simulation to Qucs allows this limitation to be largely eliminated, making Qucs-0.0.19S, a viable choice for research and industrial circuit design [9], [10].

II. AN OVERVIEW OF QUCS-0.0.19S COMPONENT MODELS

The Spice4qucs subsystem is designed for the simulation of Qucs circuit schematics with Ngspice or Xyce launched as external simulation engines [11]. In general legacy Qucs circuit doesn't require tweaking to simulate it with Qucs-0.0.19S. Qucs legacy passive components can be simulated with Qucs-0.0.19S. In addition Qucs-0.0.19S introduces a group of passive component models with SPICE format. Qucs legacy semiconductor device models are SPICE incompatible. Similar to passive components active device models have a fixed list of named parameters [1], [12]. Moreover, some of these are SPICE incompatible. Qucs-0.0.19S allows users to construct SPICE device definitions from a name, a model specifier and a SPICE style "modelcard". These can be attached to a schematic symbol and passed directly to a SPICE kernel. Qucs-0.0.19S subcircuit and library components form part of a file component subclass. These allow the construction of more complex components from pre-defined model primitives and manufactures models. Qucs-0.0.19S allows users access to the following types of file component:

- 1) *Subcircuits*, for the construction of new components from predefined components. This form of subcircuit is identical to the original Qucs implementation [12], except that each subcircuit is stored as a .SUBCKT netlist;

- 87 2) *SPICE file* components, for attaching SPICE .SUBCKTs
 88 to a circuit schematic. This component allows to pass
 89 unmodified SPICE netlist directly to simulator. Netlist
 90 is stored in a separate file;
 91 3) *Library components*, for the storage and recall of
 92 previously defined component and device models.
 93 Qucs/Qucs-0.0.19S libraries are encoded in text XML
 94 format. Library can store unmodified SPICE code.

95 III. THE OPERATION PRINCIPLES OF MULTI-SIMULATOR
 96 SUPPORT IN QUCS-0.0.19S

97 Algorithm 1 outlines the Qucs netlist building method.
 98 Qucsator does not use netlist sections [12]. A Qucs schematic
 99 is represented as a C++ class, consisting of a set of netlist pro-
 100 cessing methods. A single method scans a schematic file in one
 101 pass and outputs information describing located components.

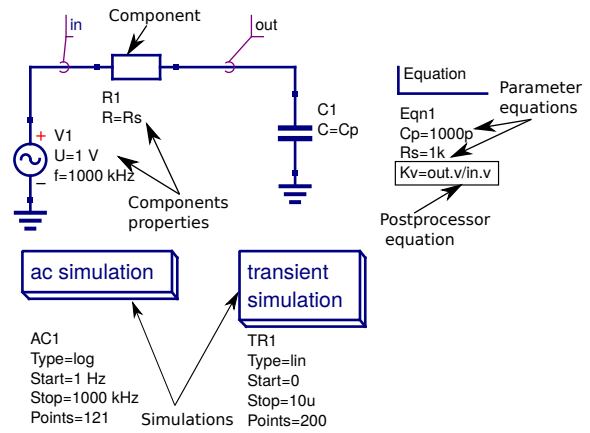

Fig. 1. A Qucs RC circuit schematic with netlist sections labelled

Algorithm 1:

```

102 Data: Qucs Schematic
103 Data: Qucs netlist filename
104 Result: Qucs netlist
105 begin
106   foreach (Component in Schematic) do
107     Netlist ← Component.getQucsNetlist()
108   end
109 end
  
```

103 In contrast, SPICE netlists consist of separate
 104 sections for equations, post-processor directives, and
 105 component specifications. Hence, building a SPICE
 106 netlist requires a multiple pass method, see Algorithm 2.

Algorithm 2:

```

107 Data: Qucs Schematic
108 Data: SPICE netlist filename
109 Result: SPICE netlist
110 begin
111   foreach (Component in Schematic) do
112     if (Component is Parameter or directive) then
113       Netlist ← Component.getSpiceExpression()
114     end
115   end
116   foreach (Component in Schematic) do
117     if (Component is Device) then
118       Netlist ← Component.getSpiceNetlist()
119     end
120   end
121   // begin of .control section
122   foreach (Component in Schematic) do
123     if (Component is Simulation) then
124       Netlist ← Component.getBeforeSimScript()
125       Netlist ← Component.getSpiceNetlist()
126       Netlist ← Component.getAfterSimScript()
127       foreach (Component in Schematic) do
128         // find equations attached to simulation
129         if (Component is Equation) then
130           Netlist ← Component.getEquation()
131         end
132       end
133     end
134   end
135   // end of .control section
136 end
  
```

The Qucs netlist for the RC network is:

```

116 # Qucs 0.0.19 RC1.sch
117 Vac:V1 in gnd U="1 V" f="1000 kHz"
118 R:R1 in out R="Rs"
119 C:C1 gnd out C="Cp"
120 Eqn:Eqn1 Cp="1000p" Rs="1k"
121 Kv="out.v/in.v" Export="yes"
122 .AC:AC1 Type="log" Start="1 Hz"
123 Stop="1000 kHz" Points="121" Noise="no"
124 .TR:TR1 Type="lin" Start="0"
125 Stop="10u" Points="200"
  
```

The Ngspice netlist for the RC network is:

```

129 * Qucs 0.0.19 RC1.sch
130 * Parameters section
131 .PARAM Cp={1000p}
132 .PARAM Rs={1k}
133 * Components section
134 V1 in 0 DC 0 SIN(0 1 1000K 0 0) AC 1
135 R1 in out {RS}
136 C1 0 out {CP}
137 * Simulations execution section
138 .control
139 AC DEC 21 1 1000K
140 let Kv=V(out)/V(in)
141 * Write result to text file
142 write RC1_ac.txt v(in) v(out) Kv
143 TRAN 5e-08 1e-05 0
144 * Write result to text file
145 write RC1_tran.txt v(in) v(out)
146 exit
147 .endc
148 * Netlist ends here
149 .END
  
```

108 A Qucs schematic consists of a group of components where
 109 every item has a properties list. For example, let's consider an
 110 RC-network schematic (see Figure 1). Qucs simulation icons
 111 and equations are considered to be a special forms of compo-
 112 nent. The Qucs netlist has declarative format. During scanning
 113 Qucsator automatically separates components, equations, and
 114 simulator directives. The order has no effect on the final result.

152 Qucs output data are translated into an XML dataset when
 153 simulation finishes. The Ngspice netlist format is very close
 154 to an imperative programming language, with .PARAM di-
 155 rectives in proper order for error free evaluation. At the
 156 end of a Ngspice netlist is a .controlendc group.
 157 This group contains a Ngntumeg post-processor script that
 158 is executed after a netlist is scanned by Ngspice. During
 scanning, simulation and post-processor directives are placed
 between the control words .controlendc. The
 .controlendc group also supports Ngntumeg file
 write directives for storing simulation datasets. Ngspice
 datasets are written in the SPICE-3f5 raw-ASCII format which
 in turn are converted and saved by Qucs-0.0.19S as part of a
 Qucs XML dataset.

166 With Xyce multiple simulations are not supported. The
 167 Xyce netlist has the following format:

```

168 * Qucs 0.0.19 RC1.sch
169 .PARAM Cp={1000p}
170 .PARAM Rs={1k}
171 .PARAM R1={1k}
172 V1 in 0 DC 0 SIN(0 1 1000K 0 0) AC 1
173 R1 in out {RS}
174 C1 0 out {CP}
175 .TRAN 5e-08 1e-05 0
176 .PRINT tran format=raw file=RC1_tran.txt v(in) v(out)
177 .END
  
```

179 Spice4qucs operates at GUI level in distinct steps; netlist
 180 building followed by simulation and finally it uses a raw-
 181 ASCII output data parser to generate a Qucs XML dataset.
 182 All schematic symbols have an XML representation which is
 183 written to memory during schematic file loading.

184 As the Xyce simulator does not include a data post-
 185 processor the netlist building algorithm for Xyce is much
 186 simpler, see Algorithm 3.

187 The block diagram drawn in Figure 2 illustrates the in-
 188 teraction between schematic capture, simulation and data
 189 visualization for all used simulation backends.

190 A number of the SPICE simulation types generate Qucs
 191 incompatible output datasets, implying that they require unique
 192 custom parsers. The parsers implemented in the current ver-
 193 sion of Qucs-0.0.19S are for SPICE-3f5 raw-ASCII (AC,
 194 DC, TRAN, and Parameter sweep simulation), Fourier sim-
 195 ulation, noise simulation and HB simulation (XYCE only).
 196 The Spice4qucs subsystem extracts output data from each
 197 simulation request and combines them into single Qucs XML
 198 dataset ready for processing by the Qucs data visualization
 199 system.

Algorithm 3:

```

Data: Qucs Schematic
Data: SPICE netlist filename
Result: SPICE netlist
begin
  foreach (Component in Schematic) do
    if (Component is Parameter or directive) then
      Netlist ← Component.getSpiceExpression()
    end
  end
  foreach (Component in Schematic) do
    if (Component is Device or Simulation) then
      Netlist ← Component.getSpiceNetlist()
    end
  end
end
  
```

IV. QUCS-0.0.19S SIMULATIONS

A. Common simulations and simulation data postprocessing

203 The following simulation types are implemented .DC, .AC,
 204 .TRAN, .FOUR, .DISTO, .NOISE, and a new "Nngspice cus-
 205 tom" form. XYCE backend supports single-tone and multitone
 206 Harmonic Balance simulation. Qucs allows to get access to
 207 these simulations from the GUI.

208 The Qucs data post-processor has many SPICE incom-
 209 patible functions. A way to overcome this is to pass post-
 210 processor directives directly to Nutmeg via a new component
 211 called "Nutmeg equation". Illustrated in Figure 3 is an RC
 212 network driven by an AC source. This demonstrates how
 213 .AC and .TRAN are defined and how "Nutmeg" can be used

Fig. 2. Spice4qucs subsystem dataflow block diagram

to determine, apparent, active and reactive power, given by
 $S = |U \cdot \bar{I}|$, $P = \Re[U \cdot \bar{I}]$, $Q = \Im[U \cdot \bar{I}]$, respectively.
 Similarly, real power can be calculated from transient data,
 using $P(t) = u(t) \cdot i(t)$.

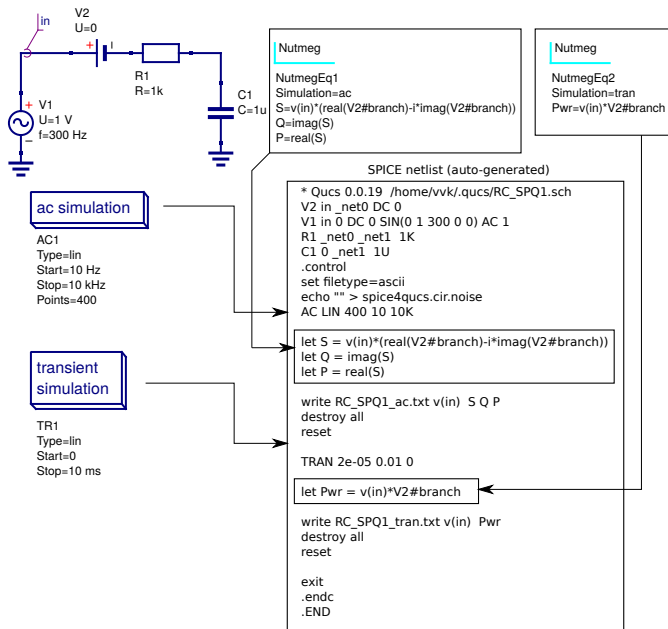

Fig. 3. An example of Nutmeg post-processor equation usage

B. Ngnutmeg scripting

214 Qucs-0.0.19S has a powerful new feature, called "Nngspice
 215 custom simulation", where a Nutmeg script is added to a Qucs
 216 schematic, allowing SPICE statements and Ngnutmeg scripts
 217 to be passed directly to a SPICE netlist.

223 It allows to get easy access to all Ngnutmeg functions from
 224 the GUI. It's able to construct nonstandard simulations using
 225 Ngnutmeg scripting (for example scattering matrix and SWR
 226 analysis, Monte-Carlo analysis).

227 For example, Z-parameter analysis is not available for the
 228 most of SPICE-compatible simulators including proprietary
 229 ones. But it could be easily constructed with Qucs-S, Ngspice,
 230 and Nutmeg scripting. Figure 4 illustrates this approach for a
 231 passive low-pass Butterworth LC-filter.

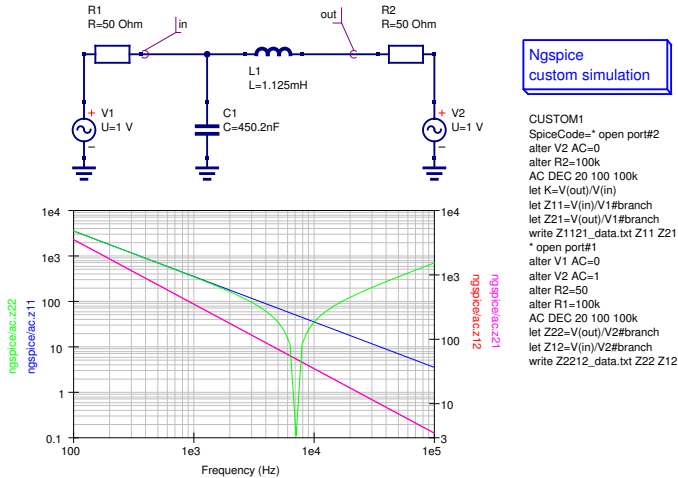

Fig. 4. Z-parameter extraction with Nutmeg scripting

232 Postprocessor directives are used to extract voltage and
 233 current data from AC-simulation results and convert it into
 234 desired Z-parameter value.

235 V. XSPICE SUPPORT IN QUCS-S

236 XSPICE is SPICE-3f5 extension targeted on system-level
 237 circuit design tasks. It is especially important for commu-
 238 nication equipment. XSPICE introduces a set of additional
 239 analog and mixed-signal models targeted on system-level
 240 design. Qucs-S with Ngspice backend supports a wide range
 241 of XSPICE blocks.

242 The following XSPICE analog devices are presented in
 243 Qucs-S out-of-box: gain block, integrator, differentiators,
 244 adder, multiplier.

245 These blocks allows simulate not only analog circuits, but
 246 also to solve control theory tasks. For example, PI-controller
 247 step response analysis is shown in the Figure 5.

248 This simulation uses XSPICE blocks (analog gain, integra-
 249 tor, and adder) to define PI-controller elements and transient
 250 simulation to obtain step response.

251 It's able to construct a new XSPICE block using "XSPICE
 252 generic device" component (Figure 7). It's sufficient to provide
 253 port list and modelcard reference to create new device. It's
 254 able to attach user symbol to a new device using standard
 255 Qucs subcircuit technique [12].

256 XSPICE allows to develop new devices using CodeModel
 257 technique [13]. User can compile a set of CodeModels in
 258 a single dynamic-loadable binary library. Now it's available
 259 inclusion of precompiled CodeModel libraries using special

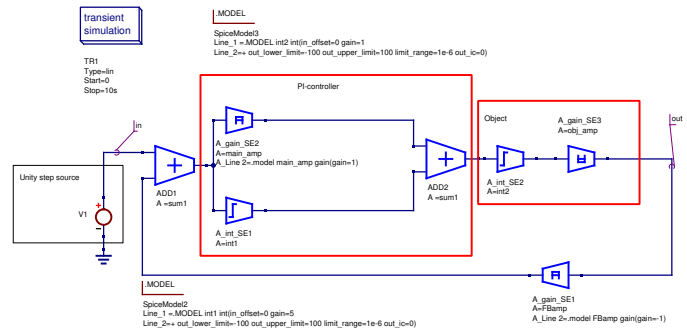

Fig. 5. PI-controller analysis with XSPICE analog blocks

Fig. 6. Simulated step response of PI-controller

260 circuit symbol (Figure 7). It's sufficient to specify location of
 261 binary library file. New models from this library could be used
 262 using user-defined XSPICE block and general modelcard.

263 Qucs-S will allow to attach CodeModels to schematic and
 264 compile it automatically during netlist building. This feature is
 265 under construction now and it will not be considered further.

266 VI. CONCLUSION

267 Qucs-0.0.19S is the first step in the development of an open-
 268 source circuit simulator that combines, and extends, the best
 269 features available with GPL circuit simulators. It can simulate
 270 a wide range of different size circuits, including those designed
 271 using manufacturer's device models.

272 Qucs-0.0.19S allows switching of simulation backends.
 273 Qucs-S covers the following application areas:

- 274 1) Realistic analog circuit simulation in time domain with
 275 Ngspice backend. Full support of SPICE-3f5 standard
 276 allows to use wide range of component models provided
 277 by vendors;
- 278 2) RF-circuits analysis (S,Z,Y-parameters matrix) using
 279 Nutmeg scripting and Harmonic balance analysis with
 280 XYCE backend [14]. This application is not available
 281 for many other SPICE-compatible simulators;
- 282 3) Control theory applications using XSPICE analog
 283 blocks;

The main advantages of Qucs-0.0.19S are:

- 284 1) It's free and open-source. It allows users to easily modify
 285 sources and propose new features;

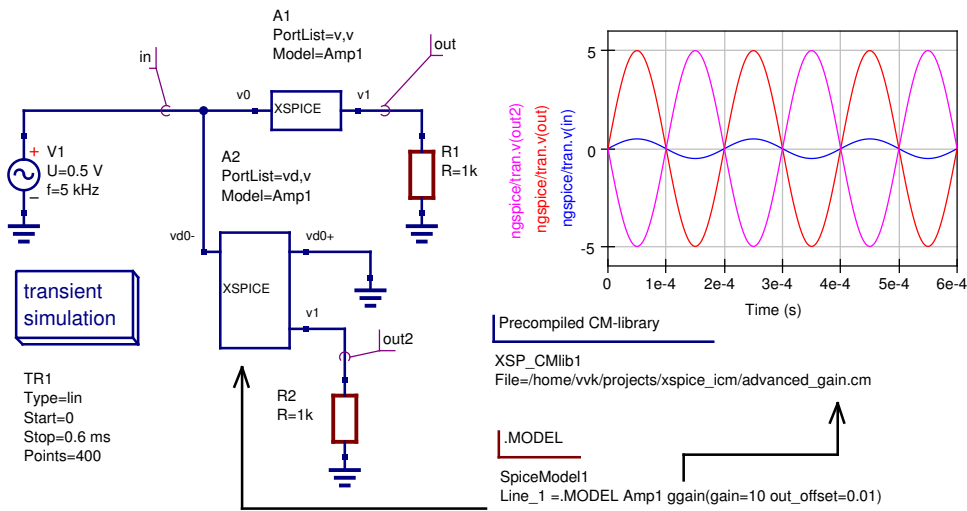

Fig. 7. User-defined XSPICE device construction

- 287 2) Switchable simulation backends allows user to select the
288 most suitable one for every simulation task;
- 289 3) Advanced postprocessing with Nutmeg Equations;
- 290 4) GUI allows to get access to unlimited features of Nut-
291 meg scripting. It allows user to construct new simulation
292 types (for example RF simulation types) without modifi-
293 cation of Qucs and simulator backends sources;
- 294 5) XSPICE allows system-level design. Also CodeModel
295 technique allows to construct new XSPICE devices
296 without modification of simulator sources.

297 Considering all above, we can conclude that Qucs-0.0.19S
298 is not simple GUI for SPICE backends. It allows also ad-
299 vanced features in simulation result postprocessing, circuit
300 parametrization, and user devices and simulation definition.
301 And Qucs-0.0.19S could be recommended for communication
302 and control equipment hardware design tasks.
